
Segments show the deviation from the scenario mean per attribute (mean over all 12 scenarios, per group), not the absolute contribution. Their sum is U − mean(U);
the diamond marks this sum and is read as true total utility on the top axis. Bars: posterior-mean coefficients (= posterior mean of the per-draw contributions). Absolute contributions: Fig. A1.
National attribute values; Switzerland: DE-CH and FR-CH weighted with the survey sample shares 61:23.
Scenarios ordered by system cost change (Mellot et al. 2024, Table 3, cheapest first); EP2050+ (5 TWh winter cap): no cost value, last.
National aggregate (appendix; national attribute values, survey-sample weights) · 96% HDI · EICom prices and EUR/CHF 2025.
